

Degrees of Freedom of MIMO X Networks: Spatial Scale Invariance and One-Sided Decomposability

Hua Sun, *Student Member, IEEE*, Tiangao Gou, *Member, IEEE*, and Syed Ali Jafar, *Senior Member, IEEE*

Abstract—We show that an $M \times N$ user MIMO X network with A antennas at each node has $A \left(\frac{MN}{M+N-1} \right)$ degrees of freedom (DoF), thus resolving in this case a discrepancy between the spatial scale invariance conjecture (scaling the number of antennas at each node by a constant factor will scale the total DoF by the same factor) and a decomposability property of overconstrained wireless networks. While the best previously known general DoF outer bound is consistent with the spatial invariance conjecture, the best previously known general DoF inner bound, inspired by the K user MIMO interference channel, was based on the decomposition of every transmitter and receiver into multiple single antenna nodes, transforming the network into an $AM \times AN$ user SISO X network. While such a decomposition is DoF optimal for the K user MIMO interference channel, a gap remained between the best inner and outer bounds for the MIMO X channel. Here we close this gap with the new insight that the MIMO X network is only one-sided decomposable, i.e., either all the transmitters or all the receivers (but not both) can be decomposed by splitting multiple antenna nodes into multiple single antenna nodes without loss of DoF. The result is extended to SIMO and MISO X networks as well and in each case the DoF results satisfy the spatial scale invariance property.

Index Terms—Capacity, degrees of freedom (DoF), interference alignment, X networks.

I. INTRODUCTION

THE use of multiple antennas, known as multiple input multiple output (MIMO) technology, and the consolidation of interference, known as interference alignment (IA), are two of the promising advances of the last two decades that seek to alleviate the spectrum shortage for wireless communication networks by making available additional spatial degrees of freedom (DoF). Taken individually, the understanding of MIMO is by now quite mature, and rapid advances have recently been made in understanding the essential principles of IA through DoF studies of a variety of network settings.

Taken together, however, the understanding of MIMO in conjunction with IA—the understanding of the spatial dimension per se—is limited by a number of unresolved fundamental issues. In terms of systematic insights, a number of properties have been identified in [2] that are true for all known DoF results, and conjectured to be true in general (i.e., for almost all channel realizations), but for which a general proof (or counter-example) is not yet known. These observations include the duality property (reciprocal networks have the same DoF), the diversity property (time-varying channels have the same DoF as constant channels), the linearity property (linear beam-forming schemes over time-varying channels are sufficient to achieve the information theoretic DoF), and especially relevant to this paper, the properties of spatial scale invariance and decomposability. Remarkably, these two properties, which hold for all DoF results known previously, contradict each other for MIMO X networks. Resolving this curious discrepancy is an open problem that is highlighted in [3] (p. 81, Sec. 5.4). The main motivation of this work is to solve this open problem.

A. Spatial Scale Invariance and Decomposability

1) *Spatial Scale Invariance*: It is well understood that the DoF of wireless networks is scale-invariant with respect to time and frequency dimensions. Wang *et al.* have recently conjectured in [4] that the spatial dimension is similarly scale invariant:

“With perfect global channel knowledge and generic channels, if the number of antennas at each node in a wireless network is scaled by a common constant factor, then the DoF of the network (for almost all channel realizations) scale by the same factor.”

The spatial scale invariance conjecture is consistent with all known DoF results across a wide variety of networks, which includes interference networks, X networks, cellular networks, and even multihop networks [3]. In particular, we note that for the 2×2 user MIMO X channel with A antennas at each node, the DoF value is known to be $\frac{4A}{3}$ [5], [6], which scales with A and is therefore, consistent with the spatial scale invariance conjecture. Even for the $M \times N$ user MIMO X network (i.e., an X network with M transmitters and N receivers) with A antennas at each node, if $\min(M, N) \leq 2$, the DoF value is easily seen to be $A \left(\frac{MN}{M+N-1} \right)$, again spatial scale invariant [7]. However, if $\min(M, N) > 2$, the DoF remain unknown. Interestingly, the best-known DoF outer bound for this setting is consistent with the spatial invariance conjecture [7].

2) *Decomposability*: We use the term “decomposition” to refer to independent processing at each antenna, essentially splitting a multiple antenna node into multiple independent single antenna nodes. It was first used to simplify the proof of achievability in the K user symmetric (equal number of

antennas at all nodes) MIMO interference channel [8] where the DoF result obtained for the SISO setting was immediately extended to the symmetric MIMO setting by decomposing the K user MIMO interference network with A antennas at each node, into an AK user SISO interference network, where the asymptotic CJ alignment scheme [3], [8] can be applied to show that $AK/2$ DoF are achievable, without joint processing among colocated antennas at any node. Since $AK/2$ is also the DoF outer bound for the K user symmetric MIMO interference network, it is evident that the network is decomposable, i.e., no loss of DoF results from decomposing all transmitters and receivers. The decomposability property is also known to be true for K user MIMO interference networks with A_t antennas at each transmitter and A_r antennas at each receiver, giving us the optimal (information theoretic) DoF value of $\frac{A_t A_r}{A_t + A_r}$ per user, provided that $K \geq \frac{A_t + A_r}{\gcd(A_t, A_r)}$ [9], [10]. Further study of the K user MIMO interference channel by Wang *et al.* leads to the conjecture that decomposability holds in all *over-constrained* (also known as improper [11]) settings, i.e., where the information theoretic DoF value per user is higher than $\frac{A_t + A_r}{K+1}$. Based on previously existing DoF results, a general pattern summarized in [3] states that:

“The DoF benefits of colocated antennas disappear with increasing number of alignment constraints.”

Evidently, this is because for overconstrained networks the multiplicity of alignment constraints invariably requires the use of the CJ scheme [3], [7], [8], which does not require joint processing across multiple antennas, instead breaking them into separate nodes. The CJ scheme is inherently a decomposition-based scheme because of its reliance on commutativity of channel matrices, a property satisfied by the diagonal channels obtained by time/frequency symbol extensions of SISO channels, but not by time/frequency extensions of MIMO channels (which would only produce noncommuting block-diagonal channels).

The previously best-known inner bound for $M \times N$ user MIMO X network with A antennas at each node, and $\min(M, N) > 2$, is also based on the decomposition argument and application of the asymptotic CJ alignment scheme [7]. By decomposing every transmitter and receiver in an $M \times N$ user MIMO X network with A antennas at each node, we obtain an $AM \times AN$ user SISO X network, and therefore the corresponding DoF value, $A \left(\frac{MN}{M+N-\frac{1}{A}} \right)$ is achievable [7].

B. Summary of Contribution

The main goal of this paper is to resolve, in the context of MIMO X networks, the apparent discrepancy between the spatial invariance conjecture, as represented by the best available DoF outer bound, and the decomposability property, as represented by the best available DoF inner bound. As mentioned above, for $M \times N$ user MIMO X network with A antennas at each node, and with $\min(M, N) > 2$, there remains a gap between the best DoF outer bound value, $A \left(\frac{MN}{M+N-1} \right)$, and the best DoF inner bound value, $A \left(\frac{MN}{M+N-\frac{1}{A}} \right)$. This gap represents an opportunity to refine our understanding of the spatial invariance and decomposability properties. While the gap may seem small for large values of A , note that because DoF is a very coarse metric, even a small gap between DoF bounds

corresponds to unbounded gaps in the corresponding capacity bounds. To summarize the motivation for this paper, MIMO X networks represent an important class of wireless networks, a precise DoF characterization is highly desirable, it would close the open problem highlighted in [3], and improve our understanding of the fundamental structure of signal dimensions.

The main contribution of this paper is the precise DoF characterization for $M \times N$ user MIMO X networks with A antennas at each node (and all SIMO and MISO X network settings). This involves both new insights as well as new technical challenges. In terms of new insights, we settle the spatial invariance conjecture for MIMO X networks with A antennas at each node, i.e., we show that the DoF outer bound is tight, also closing the heretofore open DoF problem for these networks. The discrepancy with the previous inner bound is resolved by improving our understanding of the decomposability property. We find that, unlike MIMO interference networks which demonstrate a two-sided decomposability, i.e., both the transmitters and receivers can be decomposed into single antenna nodes, MIMO X networks are only one-sided decomposable, i.e., either the transmitters or the receivers (but not both simultaneously) can be decomposed into single antenna nodes without loss of DoF. Interestingly, this is not because of the alignment constraints. Indeed the alignment still takes place very much like a SISO setting, based entirely on the CJ scheme. Instead, this is because of the separability of desired and interference signals. As it turns out, joint processing at one end, e.g., at the receivers in a SIMO X network, allows a larger space within which the desired signals can be resolved more efficiently from the interference. The use of the CJ scheme for achievability is significant because the same scheme often translates into the rational dimensions framework to establish corresponding DoF results in static settings (see, e.g., [3], [12], [13]). Indeed, the DoF results of this paper have been recently extended to constant settings by Zamanighomi and Wang in [14]. One-sided decomposability features prominently in [14] as well.

While the new insights are the key ingredient to closing this open problem, there are nontrivial technical challenges involved as well. In particular, the mathematical proof of the resolvability of desired signals from interference with joint processing across the nondecomposed receivers (the reciprocal setting follows by duality), poses new challenges. This requires proving the full rank property of a matrix (signal space matrix) whose columns represent the received signal vectors and whose rows represent the receive antennas and channel uses. What complicates matters is that this matrix contains dependencies across both rows and columns. The dependencies across rows arise because of the multiple receive antennas that receive different linear combinations of the same set of symbols over each channel use. The dependencies across columns arise due to the X setting, because each channel coefficient is involved with both desired and interfering signals. When taken individually, the dependencies across rows have been addressed in the MIMO interference network setting by Gou and Jafar in [9] and the dependencies across columns have been addressed in the X network setting by Cadambe and Jafar in [7]. However, as it turns out, dealing with both kinds of dependencies simultaneously is especially challenging. Our proof relies on a slightly modified CJ scheme, and uses mathematical induction to construct the overall signal

space matrix in a stepwise manner by appending blocks of rows and columns while at each stage proving that this does not introduce rank deficiencies.

II. SYSTEM MODEL

An $M \times N$ user MIMO X network is a single-hop communication network with M transmitters and N receivers, where Transmitter i has a message $W^{[ji]}$ for Receiver j , for each $i \in \{1, 2, \dots, M\}, j \in \{1, 2, \dots, N\}$. Transmitter i has A_i antennas and Receiver j has B_j antennas. The $M \times N$ user MIMO X network is described by input-output relationship

$$\mathbf{Y}^{[j]}(\kappa) = \sum_{1 \leq i \leq M} \mathbf{H}^{[ji]}(\kappa) \mathbf{X}^{[i]}(\kappa) + \mathbf{Z}^{[j]}(\kappa), \quad j \in \{1, 2, \dots, N\}$$

where κ represents the channel use index, $\mathbf{X}^{[i]}(\kappa)$ is the $A_i \times 1$ input signal vector of the i th Transmitter, $\mathbf{Y}^{[j]}(\kappa)$ is the $B_j \times 1$ output signal vector of the j th Receiver and $\mathbf{Z}^{[j]}(\kappa)$ represents the $B_j \times 1$ additive white Gaussian noise (AWGN) vector at the j th Receiver. The average transmit power at each transmitter is bounded by ρ (referred to as the SNR) and the i.i.d. noise variance at all receivers is assumed to be equal to unity. $\mathbf{H}^{[ji]}(\kappa)$ represents the $B_j \times A_i$ channel matrix between Transmitter i and Receiver j over the κ th channel use. We assume that all channel coefficient values are time-varying, i.i.d., drawn from a continuous distribution and the absolute value of all the channel coefficients is bounded between a nonzero minimum value and a finite maximum value. Perfect knowledge of all channel coefficients is available to all transmitters and receivers.¹ Let $R_{ji}(\rho) = \frac{\log |W^{[ji]}(\rho)|}{\kappa_0}$ denote the rate of the codeword encoding the message $W^{[ji]}$, where $|W^{[ji]}(\rho)|$ is the size of the message set and κ_0 is the length of the codeword. The rate $R_{ji}(\rho)$ is said to be achievable if for message $W^{[ji]}$, the probability of error can be made arbitrarily small with appropriately large κ_0 . The closure of all achievable rate tuples is known as the capacity region. The DoF for message $W^{[ji]}$ is defined as $d_{ji} = \lim_{\rho \rightarrow \infty} R_{ji}(\rho) / \log(\rho)$, which can be interpreted as the number of independent signaling dimensions available for $W^{[ji]}$. Analogous to the capacity region, the DoF region \mathcal{D} is the closure of the set of all achievable DoF tuples. The sum-DoF value is defined as $\max_{\mathcal{D}} \sum_{1 \leq i \leq M, 1 \leq j \leq N} d_{ji}$.

III. RESULTS

In this section, we present the statements of the main results along with some expository discussion. The proofs are relegated to Section IV.

A. Spatial Scale Invariance and Decomposability

The main result is presented in the following theorem.

Theorem 1: The $M \times N$ user MIMO X network with A antennas at each node has $A \left(\frac{MN}{M+N-1} \right)$ total DoF almost surely.

While a detailed proof appears in Section IV-B, let us convey the essence of the achievable scheme through a simple example presented in a manner consistent with the tutorial [3]. Consider

¹It is worth mentioning that due to idealized assumptions such as perfect channel knowledge, and high SNR limits, DoF studies such as this one, have more to do with mathematical insights into the fundamental notion of signal dimensions, than with immediate practical applications.

Fig. 1. IA after one-sided decomposition on the 3×3 MIMO X channel.

the 3×3 MIMO X network with two antennas at each node, i.e., $M = N = 3, A = 2$, as shown in Fig. 1. We split all the transmit antennas and view them as six independent transmitters. Each virtual transmitter selects the same beamforming matrices (thereby same signal space) $\mathbf{V}_a, \mathbf{V}_b, \mathbf{V}_c$, for Receiver a, b, c , respectively, over n symbol extensions. The signal space seen by each receiver has $2n$ dimensions. Consider the symbols desired by Receiver a , which constitute interference at Receivers b, c . These symbols are transmitted by each transmitter along the signal space designated as \mathbf{V}_a . Note that because each receiver has two antennas while each (decomposed) transmitter has only one antenna, the symbols sent from any two transmitters cannot align with each other at any receiver. In other words, one-to-one alignments are not possible. Therefore, in order to consolidate the interference caused by \mathbf{V}_a at Receivers b, c as much as possible, we turn to a many-to-many alignment scheme. Specifically, the \mathbf{V}_a spaces from Transmitters 1, 2 occupy $2|\mathbf{V}_a|$ dimensional interference space at each undesired receiver (Receivers b and c) and all the remaining undesired \mathbf{V}_a space signals sent from Transmitters 3 to 6 are incorporated into these $2|\mathbf{V}_a|$ dimensions. As shown in Fig. 1, let us set the interference space occupied by signals sent along \mathbf{V}_a , as seen by Receivers b, c , to $\mathbf{V}_a \times \mathbf{V}_a$, i.e., the column span of the matrix

$$\begin{bmatrix} \mathbf{V}_a & \mathbf{0} \\ \mathbf{0} & \mathbf{V}_a \end{bmatrix} \quad (1)$$

in which all interference will be aligned, i.e.,

$$\text{span} \begin{bmatrix} \mathbf{T}_{3i} \mathbf{V}_a \\ \mathbf{T}_{4i} \mathbf{V}_a \end{bmatrix} \subset \text{span} \begin{bmatrix} \mathbf{V}_a & \mathbf{0} \\ \mathbf{0} & \mathbf{V}_a \end{bmatrix} \quad \forall i = 1, 2, \dots, 6 \quad (2)$$

and

$$\text{span} \begin{bmatrix} \mathbf{T}_{5i} \mathbf{V}_a \\ \mathbf{T}_{6i} \mathbf{V}_a \end{bmatrix} \subset \text{span} \begin{bmatrix} \mathbf{V}_a & \mathbf{0} \\ \mathbf{0} & \mathbf{V}_a \end{bmatrix} \quad \forall i = 1, 2, \dots, 6, \quad (3)$$

where \mathbf{T}_{ji} denote the interference-carrying matrices (same as $\mathbf{H}^{[ji]}$ in the figure). All of these alignment conditions can be satisfied with the CJ alignment scheme [3]²

$$\mathbf{V}_a \approx \mathbf{T}_{ji} \mathbf{V}_a, \quad \forall i = 1, 2, \dots, 6, j = 3, 4, 5, 6. \quad (4)$$

Similarly, the three messages for Receiver b are sent along the same signal space \mathbf{V}_b by each transmitter, and align into the same space $\mathbf{V}_b \times \mathbf{V}_b$ at Receivers a, c where they constitute interference. Lastly, $\mathbf{V}_c \times \mathbf{V}_c$ spans the total interference space

²The notation $\mathbf{V}_a \approx \mathbf{T}_{ji} \mathbf{V}_a$ means that $\frac{\dim(\text{span}(\mathbf{V}_a) \cap \text{span}(\mathbf{T}_{ji} \mathbf{V}_a))}{\dim(\text{span}(\mathbf{V}_a) \cup \text{span}(\mathbf{T}_{ji} \mathbf{V}_a))}$ asymptotically approaches 1.

due to the messages intended for Receiver c , as seen by Receivers a, b . The size of the signal spaces are chosen to be equal, i.e., $|\mathbf{V}_a| = |\mathbf{V}_b| = |\mathbf{V}_c| = |\mathbf{V}|$, and $|\mathbf{V} \times \mathbf{V}| = 2|\mathbf{V}|$. We can easily see that at each receiver, desired signals from all six transmitters occupy $6|\mathbf{V}|$ dimensions, and interference (namely signals intended for the other two receivers) occupies $4|\mathbf{V}|$ dimensions. After aligning the interference, we need to guarantee the linear independence of desired signals from interference. This is proved in Section IV-B.

For the desired and interference spaces to be linearly independent, we need the size of the total signal space, $2n$, to be big enough to accommodate both. This is accomplished by setting $10|\mathbf{V}| = 2n$. The total accessible DoF for the network equal $\frac{3 \times 6|\mathbf{V}|}{n} = \frac{18}{5} = A \left(\frac{MN}{M+N-1} \right)$, as desired.

The statement of Theorem 1 can be further generalized to SIMO and MISO settings, as in Theorem 2.

Theorem 2: The $M \times N$ user SIMO X network with a single antenna at each transmitter and R antennas at each receiver, as well as its reciprocal channel, the $N \times M$ MISO X network, almost surely has a total of

$$\text{DoF} = \min \left(M, \frac{MNR}{M + NR - R} \right).$$

In addition, the DoF in both cases satisfy the spatial scale invariance property.

Note that Theorem 1 is a special case of Theorem 2 when $R = 1$ and the scaling factor is specified by A .

IV. PROOFS: SPATIAL SCALE INVARIANCE AND DECOMPOSABILITY OF MIMO X NETWORKS

We only need to prove Theorem 2 which includes Theorem 1 as a special case, as stated before. The outer bound proof, presented next, is straightforward and is provided mainly for completeness. The main challenging aspect is the achievability proof presented subsequently.

A. Outer Bound on the DoF of MIMO X Networks

The $M \times N$ user SIMO X network with a single antenna at each transmitter and R antennas at each receiver is considered. The proof for its reciprocal setting, the $N \times M$ MISO X network, follows along the same lines.

Proof: When $M \leq R$, the DoF value for the X network is bounded by the total number of transmit antennas M , which is simply the single-user DoF bound.

When $M > R$: If we allow full cooperation among the first R transmitters, then it is equivalent to the X network with $M - R + 1$ transmitters, the first transmitter equipped with R antennas and all the other transmitters equipped with single antenna each, and N receivers, each equipped with R antennas. In [7], it is shown that in X network, the number of DoF achieved

by all the messages associated with Transmitter m or Receiver n is upper bounded by $\max(A_m^t, B_n^r)$, where A_m^t and B_n^r stand for the number of antennas at Transmitter m and Receiver n , respectively. Since allowing cooperation among transmitters does not hurt the capacity, the number of DoF achieved by all the messages associated with the first R transmitters and Receiver n is no more than $\max(R, R) = R$. This gives us the outer bound

$$\sum_{q=1}^N \sum_{m=1}^R d_{qm} + \sum_{p=R+1}^M d_{np} \leq R. \quad (5)$$

Repeating the arguments for every R transmitters and each receiver, we arrive at the outer bound of the SIMO X network

$$\sum_{i \in \{1, 2, \dots, M\}, j \in \{1, 2, \dots, N\}} d_{ji} \leq \frac{MNR}{M + NR - R}. \quad (6)$$

Furthermore, the spatial scaling property of the outer bound is obvious from the derivation presented above.

B. Inner Bound on the DoF of MIMO X Networks

As mentioned previously, the achievability proof of Theorem 2 is the main challenging aspect. The proof first establishes the achievable DoF for SIMO and (by reciprocity) MISO X networks, and then uses a one-sided decomposition argument to establish spatial scale invariance for this class of networks.

Proof: When $M \leq R$, beamforming and zero forcing are sufficient to achieve the DoF.

When $M > R$, the achievable scheme is based on interference alignment. Due to the reciprocity of linear beamforming-based alignment, which states that if interference alignment is feasible in the original network, then it is also feasible in the reciprocal network, and the achievable DoF are the same between the dual networks [7], [15], we only consider the SIMO case. Consider an n symbol extension of the original channel. The value of n will be specified later. The input-output relationship of the extended channel is described by

$$\mathbf{Y}^{[j]}(\kappa) = \sum_{i=1}^M \mathbf{H}^{[ji]}(\kappa) \mathbf{X}^{[i]}(\kappa) + \mathbf{Z}^{[j]}(\kappa) \quad (7)$$

$$= \sum_{i=1}^M \begin{bmatrix} \mathbf{H}_1^{[ji]}(\kappa) \\ \vdots \\ \mathbf{H}_R^{[ji]}(\kappa) \end{bmatrix} \mathbf{X}^{[i]}(\kappa) + \mathbf{Z}^{[j]}(\kappa), \quad j \in \{1, 2, \dots, N\} \quad (8)$$

where $\mathbf{X}^{[i]}(\kappa)$ is the $n \times 1$ transmitted signal vector sent from Transmitter i and $\mathbf{Y}^{[j]}(\kappa)$ is the $nR \times 1$ received signal vector at Receiver j . $\mathbf{H}_r^{[ji]}(\kappa)$ represents the $n \times n$ channel matrix from Transmitter i to the r th receive antenna of Receiver j , $r \in \{1, \dots, R\}$, as shown in (9) given at the bottom of the page.

$$\mathbf{H}_r^{[ji]}(\kappa) = \begin{bmatrix} H_r^{[ji]}(n(\kappa-1)+1) & 0 & \dots & 0 \\ 0 & H_r^{[ji]}(n(\kappa-1)+2) & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & H_r^{[ji]}(n\kappa) \end{bmatrix} \quad (9)$$

The channel-use index κ is suppressed from now on for compactness. Each transmitter selects the same beamforming matrix \mathbf{V}_j for precoding its symbols intended for Receiver j . \mathbf{V}_j is an $n \times |\mathbf{V}_j|$ matrix whose columns are beamforming directions. The number of columns of \mathbf{V}_j , i.e., the value of $|\mathbf{V}_j|$ will also be specified later in this proof. The transmit signal sent by Transmitter i is $\mathbf{X}^{[i]} = \sum_{j=1}^N \mathbf{V}_j \mathbf{x}^{[ji]}$, where $\mathbf{x}^{[ji]}$ is the $|\mathbf{V}_j| \times 1$ vector of $|\mathbf{V}_j|$ data streams from Transmitter i to Receiver j . The received signal at Receiver l , wherein $l \in \{1, 2, \dots, N\}$, is expressed as

$$\mathbf{Y}^{[l]} = \sum_{i=1}^M \begin{bmatrix} \mathbf{H}_1^{[li]} \\ \vdots \\ \mathbf{H}_R^{[li]} \end{bmatrix} \left(\sum_{j=1}^N \mathbf{V}_j \mathbf{x}^{[ji]} \right) + \mathbf{Z}^{[l]} \quad (10)$$

$$= \sum_{i=1}^M \sum_{j=1}^N \begin{bmatrix} \mathbf{H}_1^{[li]} \mathbf{V}_j \\ \vdots \\ \mathbf{H}_R^{[li]} \mathbf{V}_j \end{bmatrix} \mathbf{x}^{[ji]} + \mathbf{Z}^{[l]} \quad (11)$$

$$= \underbrace{\sum_{i=1}^M \begin{bmatrix} \mathbf{H}_1^{[li]} \mathbf{V}_l \\ \vdots \\ \mathbf{H}_R^{[li]} \mathbf{V}_l \end{bmatrix} \mathbf{x}^{[li]}}_{\text{Desired Signal}} + \underbrace{\sum_{i=1}^M \sum_{j=1, j \neq l}^N \begin{bmatrix} \mathbf{H}_1^{[li]} \mathbf{V}_j \\ \vdots \\ \mathbf{H}_R^{[li]} \mathbf{V}_j \end{bmatrix} \mathbf{x}^{[ji]}}_{\text{Interference}} + \mathbf{Z}^{[l]}. \quad (12)$$

Consider the symbols desired by Receiver 1, which constitute interference at Receiver $l \in \{2, \dots, N\}$. These symbols are sent by each transmitter along the signal space designated as \mathbf{V}_1 . Note that because each receiver has R antennas while each transmitter has only one antenna, the symbols sent from any R transmitters cannot align among themselves at any receiver. This is because the channel matrix from any R transmitters to the R -antenna receiver is invertible almost surely. Therefore, the \mathbf{V}_1 spaces from Transmitters $1, \dots, R$, occupy an $R|\mathbf{V}_1|$ dimensional interference space at each undesired Receiver $l \in \{2, \dots, N\}$. All the remaining undesired \mathbf{V}_1 space signals sent from Transmitters $R+1, \dots, M$, are now aligned into these $R|\mathbf{V}_1|$ dimensions as follows.

Let us choose \mathbf{V}_1 to satisfy the following alignment conditions:

$$\mathbf{V}_1 \approx \mathbf{H}_1^{[li]} \mathbf{V}_1 \approx \dots \approx \mathbf{H}_R^{[li]} \mathbf{V}_1, \quad l \in \{2, \dots, N\}, i \in \{1, \dots, M\}. \quad (13)$$

Then, all the interference due to signals sent along \mathbf{V}_1 , as seen by receivers 2 to N , will be aligned into the vector space $\underbrace{\mathbf{V}_1 \times \dots \times \mathbf{V}_1}_{R \text{ times}}$, i.e.,

$$\text{span} \begin{bmatrix} \mathbf{H}_1^{[li]} \mathbf{V}_1 \\ \vdots \\ \mathbf{H}_R^{[li]} \mathbf{V}_1 \end{bmatrix} \approx \text{span} \begin{bmatrix} \mathbf{V}_1 & \mathbf{0} & \dots & \mathbf{0} \\ \mathbf{0} & \mathbf{V}_1 & \dots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{V}_1 \end{bmatrix}, \quad l \in \{2, \dots, N\}, i \in \{1, \dots, M\}. \quad (14)$$

Similarly, the N messages for Receiver j are sent along the same signal space \mathbf{V}_j by each transmitter and aligned into the same space $\mathbf{V}_j \times \dots \times \mathbf{V}_j$ at Receivers $l \in \{1, \dots, j-1, j+1, \dots, N\}$, where they constitute interference. Then, we have

$$\mathbf{V}_j \approx \mathbf{H}_r^{[li]} \mathbf{V}_j, \quad l \in \{1, \dots, j-1, j+1, \dots, N\}, \quad i \in \{1, \dots, M\}, r \in \{1, \dots, R\}. \quad (15)$$

Define $\mathcal{I}_j = \bigcup_{l,i,r} \mathbf{H}_r^{[li]} \mathbf{V}_j$, which is the union of all interference terms due to signals transmitted along \mathbf{V}_j . The conditions (13), (15) can now be expressed as $\mathbf{V}_j \approx \mathcal{I}_j$. These conditions are satisfied simultaneously by the CJ scheme construction

$$\mathbf{V}_j = \left\{ \left(\prod_{l,i,r} (\mathbf{H}_r^{[li]})^{\alpha_r^{[li]}} \right) \mathbf{1} : \sum_{l,i,r} \alpha_r^{[li]} \leq m, \alpha_r^{[li]} \in \mathbb{Z}_+, \right. \\ \left. l \in \{1, \dots, j-1, j+1, \dots, N\}, \right. \\ \left. i \in \{1, \dots, M\}, r \in \{1, \dots, R\} \right\}, \quad (16)$$

$$\mathcal{I}_j = \left\{ \left(\prod_{l,i,r} (\mathbf{H}_r^{[li]})^{\alpha_r^{[li]}} \right) \mathbf{1} : \sum_{l,i,r} \alpha_r^{[li]} \leq m+1, \alpha_r^{[li]} \in \mathbb{Z}_+, \right. \\ \left. l \in \{1, \dots, j-1, j+1, \dots, N\}, \right. \\ \left. i \in \{1, \dots, M\}, r \in \{1, \dots, R\} \right\} \quad (17)$$

where $\mathbf{1}$ is the $n \times 1$ all 1 column vector and \mathbb{Z}_+ consists only of strictly positive integers (i.e., 0 is not included). Thus, \mathbf{V}_j contains product terms up to degree m and interference \mathcal{I}_j contains product terms up to degree $m+1$. The size of the signal space \mathbf{V}_j (number of column vectors in \mathbf{V}_j) and interference \mathcal{I}_j , respectively, is

$$|\mathbf{V}_j| = \binom{m}{L}, \quad |\mathcal{I}_j| = \binom{m+1}{L} \quad (18)$$

where $L = MR(N-1)$ is the total number of interference carrying channels. We denote $|\mathbf{V}_j|$ as $|\mathbf{V}|$ and $|\mathcal{I}_j|$ as $|\mathcal{I}|$, because they are the same for all j . Notice

$$\frac{|\mathbf{V}|}{|\mathcal{I}|} = \frac{m+1-L}{m+1} \rightarrow 1 \text{ as } m \rightarrow \infty \quad (19)$$

which means $|\mathbf{V}| \approx |\mathcal{I}|$. At Receiver j , desired signals occupy $M|\mathbf{V}|$ dimensions and aligned interference occupies $(N-1)R|\mathcal{I}|$ dimensions. To avoid overlaps between desired signals and interference, the size of receive signal space, nR , must be at least as big as the sum of the dimensions of desired signals and interference, $nR \geq M|\mathbf{V}| + R(N-1)|\mathcal{I}|$, so we set $n = M|\mathbf{V}|/R + (N-1)|\mathcal{I}|$.³

Next we prove the linear independence of the desired signals from interference.

Let us first simplify the notation as follows. Relabel all the L interference carrying channels $\mathbf{H}_r^{[li]}$ in \mathbf{V}_j as \mathbf{T}_1 to \mathbf{T}_L and

³One can guarantee that n is an integer by, e.g., choosing $m = LRz$ wherein z is the sequence of integers, so that $|\mathbf{V}| = Rz \binom{LRz-1}{L-1}$ is divisible by R .

their corresponding exponents as α_1 to α_L . Similar change of notation is also done within all \mathcal{I}_j . Then,

$$\mathbf{V}_j = \left\{ (\mathbf{T}_1)^{\alpha_1} (\mathbf{T}_2)^{\alpha_2} \cdots (\mathbf{T}_L)^{\alpha_L} \mathbf{1}, \right. \\ \left. \text{s.t. } \sum_{i=1}^L \alpha_i \leq m, \alpha_1, \dots, \alpha_L \in \mathbb{Z}_+ \right\}. \quad (20)$$

Note that \mathbf{V}_j is comprised of column vectors. For ease of exposition, we will impose a lexicographic order on these columns in the representation of \mathbf{V}_j , as follows. First, we arrange all columns from left to right in increasing order of α_1 . Then for columns of the same α_1 , we will arrange them in increasing order of α_2 . In general, given the same tuple $(\alpha_1, \alpha_2, \dots, \alpha_k)$, $k < L$, we will arrange these columns in increasing order of α_{k+1} . For example, consider the setting $L = 3$ and $m = 5$. Then, a row of \mathbf{V}_j is represented as

$$[T_1 T_2 T_3 \quad T_1 T_2 T_3^2 \quad T_1 T_2 T_3^3 \quad T_1 T_2^2 T_3 \quad T_1 T_2^2 T_3^2 \cdots \\ T_1 T_2^3 T_3 \quad T_1^2 T_2 T_3 \quad T_1^2 T_2 T_3^2 \quad T_1^2 T_2^2 T_3 \quad T_1^3 T_2 T_3]. \quad (21)$$

Such an ordering has the property that a tuple $(\alpha_1, \alpha_2, \dots, \alpha_L)$ appears before the tuple $(\beta_1, \beta_2, \dots, \beta_L)$ if and only if the first α_i , which is different from β_i , is smaller than β_i . With this arrangement, we have the following lemma.

Lemma 1: Consider a row vector

$$\mathbf{v}_{j:k} = [V_1 \quad V_2 \quad \cdots \quad V_k] \quad (22)$$

which is obtained from the first to the k th column of an arbitrary row of matrix \mathbf{V}_j . Now consider a product of the form $\prod_{i=1}^R V_{k_i}$ $\forall i$, $k_i \in \{1, \dots, k\}$. Note that each product is a monomial in variables of T_l , $l \in \{1, 2, \dots, L\}$. Then, $\prod_{i=1}^R V_{k_i} = (V_k)^R$ if and only if $k_i = k$, for all $i \in \{1, \dots, R\}$.

Proof: Suppose $V_k = T_1^{\alpha_1} T_2^{\alpha_2} \cdots T_L^{\alpha_L}$. Then, $V_k^R = T_1^{R\alpha_1} T_2^{R\alpha_2} \cdots T_L^{R\alpha_L}$. Suppose $\forall k_i \leq k$ we have $V_{k_i} = T_1^{\beta_1^{[k_i]}} T_2^{\beta_2^{[k_i]}} \cdots T_L^{\beta_L^{[k_i]}}$, $i \in \{1, \dots, R\}$ such that $\sum_{i=1}^R \beta_j^{[k_i]} = R\alpha_j \quad \forall j \in \{1, \dots, L\}$. According to the ordering of the V , since $k_i \leq k$, we have $\beta_1^{[k_i]} \leq \alpha_1$, for all k_i . So in order for $\sum_{i=1}^R \beta_1^{[k_i]} = R\alpha_1$, all $\beta_1^{[k_i]}$ have to be equal to α_1 . Continuing this argument, given $\beta_j^{[k_i]} = \alpha_j$ for all $j < L$, we have $\beta_{j+1}^{[k_i]} \leq \alpha_{j+1}$ for all k_i . So in order for $\sum_{i=1}^R \beta_{j+1}^{[k_i]} = R\alpha_{j+1}$, all $\beta_{j+1}^{[k_i]}$ have to be equal to α_{j+1} , leading to $V_{k_i} = V_k$. ■

Without loss of generality, we will prove the linear independence of desired and interfering signal spaces for Receiver 1. Let us define the $n \times M|\mathbf{V}|$ matrix

$$\mathbf{D}_r^{[1]} = [\mathbf{H}_r^{[11]} \mathbf{V}_1 \quad \mathbf{H}_r^{[12]} \mathbf{V}_1 \quad \cdots \quad \mathbf{H}_r^{[1M]} \mathbf{V}_1], \\ r \in \{1, \dots, R\} \quad (23)$$

which corresponds to the desired signal at the r th antenna of Receiver 1. Then the desired signal at Receiver 1 is received along the columns of the following $nR \times M|\mathbf{V}|$ matrix:

$$\mathbf{D}^{[1]} = \begin{bmatrix} \mathbf{D}_1^{[1]} \\ \mathbf{D}_2^{[1]} \\ \vdots \\ \mathbf{D}_R^{[1]} \end{bmatrix}. \quad (24)$$

Now consider the interference. According to our alignment scheme, the interference signal intended for Receiver $l \in \{2, \dots, N\}$, is aligned into the span of the columns of the following $nR \times R|\mathcal{I}|$ matrix:

$$\mathbf{E}_l = \begin{bmatrix} \mathcal{I}_l & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathcal{I}_l & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathcal{I}_l \end{bmatrix} = \mathbf{I}_R \otimes \mathcal{I}_l, \quad l \in \{2, \dots, N\} \quad (25)$$

where \mathbf{I}_R is the $R \times R$ identity matrix and \otimes denotes the Kronecker product. As a result, all interference signals are aligned into the span of the columns of the following $nR \times (N-1)R|\mathcal{I}|$ matrix:

$$\mathbf{E}^{[1]} = [\mathbf{E}_2 \quad \cdots \quad \mathbf{E}_N]. \quad (26)$$

Therefore, we need to show the $nR \times nR$ matrix $\mathbf{F}^{[1]} = [\mathbf{D}^{[1]} \quad \mathbf{E}^{[1]}]$ has full rank almost surely. We will show that the desired signals are linearly independent among themselves and the desired signal space does not overlap with the interference space, respectively.

The difficulty lies in the second step because there is dependency across both columns and rows in the signal space matrix. The columns are dependent because in X networks, desired channels for Receiver 1 are interfering channels for other receivers. The rows are dependent because we are performing joint MIMO decoding, involving signals that are received at all receive antennas. So we need to perform an induction on both columns and rows at the same time. At each induction step, assuming the original matrix has full rank, we prove that the new matrix formed by adding R columns and R rows also has full rank. This is done by identifying a distinct monomial in the polynomial expansion of the determinant. Both the block diagonal structure of the interference and the former lexicographic ordering of the precoding vectors are important in the remainder of the proof, which is described next.

Step 1: We first prove that the desired signals are linearly independent, i.e., the $nR \times M|\mathbf{V}|$ matrix $\mathbf{D}^{[1]}$ has full rank almost surely. To do this, it is sufficient to prove the following $M|\mathbf{V}| \times M|\mathbf{V}|$ submatrix of $\mathbf{D}^{[1]}$ has full rank almost surely

$$\bar{\mathbf{D}}^{[1]} = \begin{bmatrix} \bar{\mathbf{D}}_1^{[1]} \\ \bar{\mathbf{D}}_2^{[1]} \\ \vdots \\ \bar{\mathbf{D}}_R^{[1]} \end{bmatrix} \quad (27)$$

where

$$\bar{\mathbf{D}}_r^{[1]} = [\bar{\mathbf{H}}_r^{[11]} \bar{\mathbf{V}}_1 \quad \bar{\mathbf{H}}_r^{[12]} \bar{\mathbf{V}}_1 \quad \cdots \quad \bar{\mathbf{H}}_r^{[1M]} \bar{\mathbf{V}}_1], \\ r \in \{1, \dots, R\} \quad (28)$$

is comprised of the first $\frac{M|\mathbf{V}|}{R}$ rows of $\mathbf{D}_r^{[1]}$, i.e., $\bar{\mathbf{H}}_r^{[1i]}$ is a diagonal square matrix of dimension $\frac{M|\mathbf{V}|}{R} \times \frac{M|\mathbf{V}|}{R}$ obtained from the first $\frac{M|\mathbf{V}|}{R}$ rows and columns from matrix $\mathbf{H}_r^{[1i]}$ and $\bar{\mathbf{V}}_1$ is the $\frac{M|\mathbf{V}|}{R} \times |\mathbf{V}|$ matrix obtained from the first $\frac{M|\mathbf{V}|}{R}$ rows of \mathbf{V}_1 . Essentially, we only consider the signals received up to channel use index $\frac{M|\mathbf{V}|}{R}$. Note that $\bar{\mathbf{D}}^{[1]}$ has R block rows which correspond to the received signals at R receive antennas and M

block columns which correspond to the desired signals from M transmitters.

To prove that it is a full rank matrix, we will prove $\det(\bar{\mathbf{D}}^{[1]}) \neq 0$ almost surely. The determinant is a polynomial of all channel coefficients up to channel use index $\frac{M|\mathbf{V}|}{R}$. To prove that it is not equal to zero almost surely, it suffices to prove that it is not a zero polynomial, which can be proved by showing that at least one specific channel realization exists such that the polynomial is not equal to zero. We will set the channel coefficients in such a manner that $\bar{\mathbf{D}}^{[1]}$ becomes a block diagonal matrix with M blocks and each block is a full rank matrix almost surely, which leads to the conclusion that $\bar{\mathbf{D}}^{[1]}$ has full rank almost surely as well. Specifically, consider the i th block column of $\bar{\mathbf{D}}^{[1]}$, i.e., the $M|\mathbf{V}| \times |\mathbf{V}|$ matrix:

$$\begin{bmatrix} \bar{\mathbf{H}}_1^{[1i]} \bar{\mathbf{V}}_1 \\ \bar{\mathbf{H}}_2^{[1i]} \bar{\mathbf{V}}_1 \\ \vdots \\ \bar{\mathbf{H}}_R^{[1i]} \bar{\mathbf{V}}_1 \end{bmatrix}, \quad i \in \{1, \dots, M\} \quad (29)$$

which corresponds to the desired signal from Transmitter i . We set all rows except rows $(i-1)|\mathbf{V}|+1, \dots, i|\mathbf{V}|$ of (29) to zero by setting the corresponding channel coefficients in matrix $\bar{\mathbf{H}}_r^{[1i]}$ to zero. This operation involves only channels that originate at Transmitter i , so they are independent of other block columns. Note that this can be done because $\bar{\mathbf{V}}_1$ does not contain channel coefficients associated with Receiver 1. As a result, we convert matrix $\bar{\mathbf{D}}^{[1]}$ into a block diagonal matrix with M blocks and each block is a $|\mathbf{V}| \times |\mathbf{V}|$ matrix.

What remains to be shown is that each block is a full rank matrix almost surely. We will prove this by showing that each block matrix satisfies two properties: 1) every entry of each row is a distinct monomial; 2) each row is independent of the other rows. If both properties are satisfied, then it follows from Lemma 1 in [7] that the matrix has full rank almost surely. It can be easily seen that the first property is satisfied for each row due to the construction of \mathbf{V}_1 . We only need to prove the second property is satisfied as well. From (29), we know each row of $\bar{\mathbf{V}}_1$ appears periodically with period $\frac{M|\mathbf{V}|}{R}$, which corresponds to different linear combinations of the same set of symbols received at multiple antennas. Then, if we choose K consecutive rows from (29), the rows are not independent if and only if $K > \frac{M|\mathbf{V}|}{R}$. Now, we choose $|\mathbf{V}|$ consecutive rows each time and $|\mathbf{V}| < \frac{M|\mathbf{V}|}{R}$ because $R < M$. As a result, each row is independent. Therefore, each block matrix is full rank almost surely. So we have proved the desired signals are linearly independent almost surely.

Step 2: We will prove that the interference space does not overlap with the signal space. To do that we first reorder the rows and columns of matrix $\mathbf{F}^{[1]}$. The columns of each \mathbf{E}_l are reordered as follows:

$$\tilde{\mathbf{E}}_l = [\mathbf{I}_R \otimes \mathcal{I}_{l1} \quad \cdots \quad \mathbf{I}_R \otimes \mathcal{I}_{l|\mathcal{I}|}], \quad l \in \{2, \dots, N\} \quad (30)$$

where the $n \times 1$ vector \mathcal{I}_{lk} denotes the k th column of \mathcal{I}_l . Next, we arrange the rows in increasing order of the channel indices.

Over the κ th channel use, the desired signal is received along the columns of the following $R \times M|\mathbf{V}|$ matrix:

$$\mathbf{D}^{[1]}(\kappa) = \begin{bmatrix} H_1^{[11]}(\kappa) & H_1^{[12]}(\kappa) & \cdots & H_1^{[1M]}(\kappa) \\ H_2^{[11]}(\kappa) & H_2^{[12]}(\kappa) & \cdots & H_2^{[1M]}(\kappa) \\ \vdots & \vdots & \ddots & \vdots \\ H_R^{[11]}(\kappa) & H_R^{[12]}(\kappa) & \cdots & H_R^{[1M]}(\kappa) \end{bmatrix} \otimes \mathbf{V}_1(\kappa) \quad (31)$$

where the $1 \times |\mathbf{V}|$ vector $\mathbf{V}_1(\kappa)$ denotes the κ th row of \mathbf{V}_1 . The interference caused by messages intended for Receiver l over the κ th channel use is contained in the span of the columns of the following $R \times R|\mathcal{I}|$ matrix:

$$\mathbf{E}_l(\kappa) = [\mathcal{I}_{l1}(\kappa)\mathbf{I}_R \quad \mathcal{I}_{l2}(\kappa)\mathbf{I}_R \quad \cdots \quad \mathcal{I}_{l|\mathcal{I}|}(\kappa)\mathbf{I}_R], \quad l \in \{2, \dots, N\} \quad (32)$$

where the scalar $\mathcal{I}_{lk}(\kappa)$ denotes the element in the κ th row and k th column of \mathcal{I}_l . As a result, all signals are received along the columns of the following matrix over the κ th channel use:

$$\mathbf{F}^{[1]}(\kappa) = [\mathbf{D}^{[1]}(\kappa) \quad \mathbf{E}_2(\kappa) \quad \cdots \quad \mathbf{E}_N(\kappa)]_{R \times nR}. \quad (33)$$

After rearranging the rows and columns, the $nR \times nR$ matrix $\mathbf{F}^{[1]}$ becomes

$$\tilde{\mathbf{F}}^{[1]} = \begin{bmatrix} \mathbf{F}^{[1]}(1) \\ \vdots \\ \mathbf{F}^{[1]}(n) \end{bmatrix}. \quad (34)$$

Recall that in Step 1, we already proved that the desired signals are linearly independent almost surely, i.e., the first $M|\mathbf{V}|$ columns of $\tilde{\mathbf{F}}^{[1]}$ are linearly independent. This was done by proving that the $M|\mathbf{V}| \times M|\mathbf{V}|$ matrix $\bar{\mathbf{D}}^{[1]}$ has full rank almost surely. Note that $\bar{\mathbf{D}}^{[1]}$ corresponds to all rows of the desired signals up to channel use index $T = \frac{M|\mathbf{V}|}{R}$, i.e.,

$$\tilde{\mathbf{D}}^{[1]} = \begin{bmatrix} \mathbf{D}^{[1]}(1) \\ \vdots \\ \mathbf{D}^{[1]}(T) \end{bmatrix} \quad (35)$$

after row rearrangements according to channel use indices. Next, we will start from $\tilde{\mathbf{D}}^{[1]}$, and at each induction step, append R rows and R columns to its bottom and right in $\tilde{\mathbf{F}}^{[1]}$, and prove that the resulting square matrix has full rank almost surely. These R rows and R columns intersect in an $R \times R$ matrix. The blocks are added sequentially and every time the rows in the block correspond to the received signal at channel use index $T + \kappa, \kappa \in \{1, \dots, (N-1)|\mathcal{I}|\}$. We will arrive at $\tilde{\mathbf{F}}^{[1]}$ in the end. Now, let us add the first block, i.e.,

$$\begin{aligned} \mathbf{G}(1) &= \begin{bmatrix} \tilde{\mathbf{D}}^{[1]} & \mathbf{B}_{21} \\ \mathbf{D}^{[1]}(T+1) & \mathcal{I}_{21}(T+1)\mathbf{I}_R \end{bmatrix} \\ &= \begin{bmatrix} \mathbf{D}^{[1]}(1) & \mathcal{I}_{21}(1)\mathbf{I}_R \\ \vdots & \vdots \\ \mathbf{D}^{[1]}(T) & \mathcal{I}_{21}(T)\mathbf{I}_R \\ \mathbf{D}^{[1]}(T+1) & \mathcal{I}_{21}(T+1)\mathbf{I}_R \end{bmatrix}. \end{aligned} \quad (36)$$

We will now prove that the $(M|\mathbf{V}| + R) \times (M|\mathbf{V}| + R)$ matrix $\mathbf{G}(1)$ has full rank, i.e., $\det(\mathbf{G}(1)) \neq 0$ almost surely. The entries in $\mathbf{D}^{[1]}(T+1)$ and $\mathcal{I}_{21}(T+1)\mathbf{I}_R$ are independent of the entries in $\mathbf{D}^{[1]}$ and \mathbf{B}_{21} , because they correspond to different channel uses. Fix $\tilde{\mathbf{D}}^{[1]}$ and \mathbf{B}_{21} , then $\det(\mathbf{G}(1))$ is a polynomial in variables of the entries in $\mathbf{D}^{[1]}(T+1)$ and $\mathcal{I}_{21}(T+1)\mathbf{I}_R$. Each term in polynomial $\det(\mathbf{G}(1))$ is a product of R entries, each chosen from a distinct row and distinct column of $[\mathbf{D}^{[1]}(T+1) \mathcal{I}_{21}(T+1)\mathbf{I}_R]$. One of these is the term $\det(\tilde{\mathbf{D}}^{[1]})(\mathcal{I}_{21}(T+1))^R$. To prove that $\det(\mathbf{G}(1)) \neq 0$ almost surely, it is sufficient to prove that it is not a zero polynomial, which can be proved if $(\mathcal{I}_{21}(T+1))^R$ is a unique monomial. Since $\mathbf{D}^{[1]}(T+1)$ contains channel coefficients associated with Receiver 2 while $(\mathcal{I}_{21}(T+1))^R$ does not contain those coefficients, we have to choose all R entries from the $R \times R$ diagonal matrix $\mathcal{I}_{21}(T+1)\mathbf{I}_R$ to produce $(\mathcal{I}_{21}(T+1))^R$. Therefore, it is a unique monomial and $\mathbf{G}(1)$ has full rank.

We proceed similarly to add the κ th block, $\kappa \in \{2, \dots, (N-1)|\mathcal{I}|\}$, i.e.,

$$\mathbf{G}(\kappa) = \begin{bmatrix} \mathbf{G}(\kappa-1) & \mathbf{B}(\kappa-1) \\ \mathbf{C}(\kappa) & \mathcal{I}_{lk}(T+\kappa)\mathbf{I}_R \end{bmatrix} \quad (37)$$

where $l = (\lceil \frac{\kappa}{|\mathcal{I}|} \rceil + 1)$, $k = (\kappa - (l-2)|\mathcal{I}|)$ and

$$\begin{aligned} \mathbf{C}(\kappa) &= [\mathbf{D}^{[1]}(T+\kappa) \mathbf{E}_2(T+\kappa) \cdots \mathbf{E}_{l-1}(T+\kappa) \\ &\quad \cdots \mathcal{I}_{l1}(T+\kappa)\mathbf{I}_R \cdots \mathcal{I}_{l(k-1)}(T+\kappa)\mathbf{I}_R], \\ \mathbf{B}(\kappa-1) &= [\mathcal{I}_{lk}(1)\mathbf{I}_R \cdots \mathcal{I}_{lk}(T+\kappa-1)\mathbf{I}_R]^T. \end{aligned} \quad (38)$$

Next, we will use induction to prove that the $(M|\mathbf{V}| + \kappa R) \times (M|\mathbf{V}| + \kappa R)$ matrix $\mathbf{G}(\kappa)$ is full rank almost surely. Assuming $\mathbf{G}(\kappa-1)$ is full rank almost surely, we will prove $\det(\mathbf{G}(\kappa)) \neq 0$ almost surely. Notice that $[\mathbf{C}(\kappa) \mathcal{I}_{lk}(T+\kappa)\mathbf{I}_R]$ is independent of $[\mathbf{G}(\kappa-1) \mathbf{B}(\kappa-1)]$. Fix $[\mathbf{G}(\kappa-1) \mathbf{B}(\kappa-1)]$, now the determinant becomes a polynomial in variables of $\mathbf{C}(\kappa)$ and $\mathcal{I}_{lk}(T+\kappa)\mathbf{I}_R$. It is sufficient to prove that it is not a zero polynomial. Each term in the polynomial is a product of R entries, each chosen from one different row and one different column of $[\mathbf{C}(\kappa) \mathcal{I}_{lk}(T+\kappa)\mathbf{I}_R]$. And the polynomial contains the term $\det(\mathbf{G}(\kappa-1))(\mathcal{I}_{lk}(T+\kappa))^R$. If we can prove that $(\mathcal{I}_{lk}(T+\kappa))^R$ is a unique monomial, then the polynomial is not a zero polynomial since $\det(\mathbf{G}(\kappa-1)) \neq 0$, by induction assumption. We will now prove that indeed $(\mathcal{I}_{lk}(T+\kappa))^R$ is a unique monomial. Note that $(\mathcal{I}_{lk}(T+\kappa))^R$ does not contain channel coefficients associated with Receiver l while all entries in $[\mathbf{D}^{[1]}(T+\kappa) \mathbf{E}_2(T+\kappa) \cdots \mathbf{E}_{l-1}(T+\kappa)]$ contain those coefficients. Therefore, in order to make the product to be the same as $(\mathcal{I}_{lk}(T+\kappa))^R$, columns of $[\mathbf{D}^{[1]}(T+\kappa) \mathbf{E}_2(T+\kappa) \cdots \mathbf{E}_{l-1}(T+\kappa)]$ cannot be chosen. As a result, we only consider choosing R entries from different columns and rows of $[\mathcal{I}_{l1}(T+\kappa)\mathbf{I}_R \cdots \mathcal{I}_{lk}(T+\kappa)\mathbf{I}_R]$.

Essentially, the problem becomes to pick R entries each arbitrarily from the vector $[\mathcal{I}_{l1}(T+\kappa) \mathcal{I}_{l2}(T+\kappa) \cdots \mathcal{I}_{lk}(T+\kappa)]$ and prove the product is equal to $(\mathcal{I}_{lk}(T+\kappa))^R$ if and only if $\mathcal{I}_{lk}(T+\kappa)$ is chosen every time. Mathematically, we want

to prove that $\prod_{i=1}^R \mathcal{I}_{lk_i}(T+\kappa)$, $k_i \in \{1, \dots, k\}$ is equal to $(\mathcal{I}_{lk}(T+\kappa))^R$ if and only if $k_i = k$, for all $i \in \{1, \dots, R\}$. From Lemma 1, this is indeed true. Therefore, we arrive at the conclusion that $(\mathcal{I}_{lk}(T+\kappa))^R$ is a unique monomial and $\mathbf{G}(\kappa)$ has full rank almost surely. Following the induction on κ up to its final value, $\kappa = (N-1)|\mathcal{I}|$, we have $\mathbf{G}(\kappa) = \tilde{\mathbf{F}}^{[1]}$. Thus, we conclude that the interference space does not overlap with the signal space.

Therefore, the accessible DoF for each receiver equal $R \frac{M|\mathbf{V}|}{nR} = R \frac{M|\mathbf{V}|}{M|\mathbf{V}|+R(N-1)|\mathcal{I}|} \rightarrow \frac{MR}{M+NR-R}$ as $m \rightarrow \infty$, resulting in a sum DoF of $\frac{MNR}{M+NR-R}$, as desired. At this point we have completed the proof of our DoF result for SIMO and MISO X networks.

We now prove the spatial scale invariance property for extensions of MISO or SIMO X networks. Let us scale the number of antennas at each node by a factor of A and prove the DoF also scale by a factor of A . When $M \leq R$, the achievable scheme involves only zero forcing and it is easy to see that the DoF scale with A . When $M > R$, we establish spatial scale invariance for the SIMO X network by a decomposition argument and the MISO case follows by reciprocity. For the spatially scaled SIMO X network, we use transmitter side decomposition. Transmitter side decomposition means that we view each transmitter with A antennas as A distributed transmitters with a single antenna each, such that each of these A transmitters has an independent message for each of the N receivers. In other words, we do not allow joint processing of signals among the A antennas at each transmitter. Then, we obtain an $AM \times N$ user SIMO X network with a single antenna at each transmitter and AR antennas at each receiver rather than an $M \times N$ user MIMO X network with A antennas at each transmitter and AR antennas at each receiver. By the result established for SIMO X networks, $\frac{AMNAR}{AM+NAAR-AR} = A \left(\frac{MNR}{M+NR-R} \right)$ DoF are achieved almost surely. This completes the proof.

V. CONCLUSION

In this work, we close the open problem of finding the DoF of MIMO X networks with A antennas at each node. In particular, we settle the spatial scale invariance conjecture for this class of networks, as well as SIMO and MISO X networks. In terms of the achievable scheme, we reveal a one-sided decomposability property of X networks.

ACKNOWLEDGMENT

The authors would like to thank the Associate Editor, Prof. A. Lozano and the reviewers for their valuable comments.

Hua Sun (S'12) received the B.E. degree in Communications Engineering from Beijing University of Posts and Telecommunications, Beijing, China, in 2011, the M.S. degree in Electrical and Computer Engineering from University of California Irvine, USA, in 2013. He is currently pursuing the Ph.D. degree at the University of California Irvine. His research interests include multiuser information theory and wireless communications.

Tiangao Gou (S'08–M'12) received the B.E. degree in Electronic Information Engineering from University of Science and Technology Beijing, Beijing, China in 2007, the M.S. and Ph.D. degrees in Electrical and Computer Engineering from University of California Irvine, Irvine, CA USA in 2009 and 2012, respectively. He is currently a senior research engineer at Samsung Mobile Solutions Lab in San Diego, CA USA. He was a summer intern at Mitsubishi Electric Research Laboratories (MERL), Cambridge, MA, in 2010. His research interests include multiuser information theory and wireless communications.

Syed Ali Jafar (S'99–M'04–SM'09) received the B. Tech. degree from IIT Delhi, India, in 1997, M.S. from Caltech, USA, in 1999, and Ph.D. from Stanford, USA, in 2003, all in Electrical Engineering. His industry experience includes positions at Lucent Bell Labs, Qualcomm Inc. and Hughes Software Systems. He is currently an Associate Professor in the Department of Electrical Engineering and Computer Science at the University of California Irvine, Irvine, CA USA. His research interests include multiuser information theory and wireless communications.

Dr. Jafar received the NSF CAREER award in 2006, the ONR Young Investigator Award in 2008, the Information Theory Society paper award in 2009, the Maseeh Outstanding Research Award in 2010, an IEEE GLOBECOM Best Paper Award in 2012, and the IEEE Communications Society Best Tutorial Paper Award in 2013. Dr. Jafar received the UC Irvine EECS Professor of the Year award four times, in 2006, 2009, 2011 and 2012, from the Engineering Students Council and the Teaching Excellence Award in 2012 from the School of Engineering. He was a University of Canterbury Erskine Fellow in 2010 and is an IEEE Communications Society Distinguished Lecturer for 2013–2014. Dr. Jafar served as Associate Editor for the IEEE TRANSACTIONS ON COMMUNICATIONS 2004–2009, for the IEEE COMMUNICATIONS LETTERS 2008–2009 and for the IEEE TRANSACTIONS ON INFORMATION THEORY 2009–2012.
